In Python, similarity measures are widely used in data science, machine learning, natural language processing, and recommendation systems. They are used to quantify how similar two objects, vectors, or sets are. Here is a comprehensive overview of commonly used similarity measures and how to implement them in Python.

1. Cosine Similarity

Cosine similarity measures the cosine of the angle between two vectors.

```
from sklearn.metrics.pairwise import cosine_similarity
import numpy as np

vec1 = np.array([[1, 2, 3]])
vec2 = np.array([[4, 5, 6]])
similarity = cosine_similarity(vec1, vec2)
print("Cosine Similarity:", similarity[0][0])
```

2. Euclidean Distance / Similarity

Measures the straight-line distance between two vectors. Smaller distance implies higher similarity.

```
from scipy.spatial.distance import euclidean

vec1 = [1, 2, 3]
vec2 = [4, 5, 6]
distance = euclidean(vec1, vec2)
print("Euclidean Distance:", distance)
```

To convert distance to similarity: `similarity = 1 / (1 + distance)`.

3. Jaccard Similarity

Used for comparing sets. Similarity = size of intersection / size of union.

```
from sklearn.metrics import jaccard_score
import numpy as np

a = np.array([1,0,1,1])
b = np.array([1,1,0,1])
score = jaccard_score(a, b)
print("Jaccard Similarity:", score)
```

4. Pearson Correlation

Measures linear correlation between two sets of values.

```
from scipy.stats import pearsonr

x = [1, 2, 3, 4, 5]
y = [5, 4, 3, 2, 1]
corr, _ = pearsonr(x, y)
print("Pearson Correlation:", corr)
```

5. Manhattan Distance / L1 Similarity

The Manhattan distance sums the absolute differences between ele ments.

```
from scipy.spatial.distance import cityblock

vec1 = [1, 2, 3]
vec2 = [4, 0, 6]
distance = cityblock(vec1, vec2)
print("Manhattan Distance:", distance)
similarity = 1 / (1 + distance)
print("Manhattan Similarity:", similarity)
```

6. Hamming Similarity

Useful for categorical or binary data; measures the fraction of positio ns where vectors are equal.

```
from scipy.spatial.distance import hamming

vec1 = [1, 0, 1, 1]
vec2 = [1, 1, 0, 1]
similarity = 1 - hamming(vec1, vec2)
print("Hamming Similarity:", similarity)
```

Summary

Depending on data type:

- **Vectors / numeric data:** Cosine, Euclidean, Manhattan, Pearson
- **Binary / categorical data:** Jaccard, Hamming
- These measures can be easily computed using **scikit-learn**, **scipy**, or **numpy**. Combining multiple measures often improves similarity analysis in complex applications like recommendation systems or clustering.

  Usage Example: For text data, compute TF-IDF vectors first and then use cosine similarity for comparing documents.
